Abstract

Optimized Schwarz preconditioning is applied to a spectral element method for the modified Helmholtz equation and pseudo-Laplacian arising in incompressible flow solvers. The preconditioning is performed on an element-by-element basis. The method enables one to use non-overlapping elements, yielding an effective algorithm in terms of communication between elements and implementation. Two approaches are tested. The first consists of constructing a P_1 finite element problem on each overlapping element. In the second, the preconditioner is applied directly on a non-overlapping spectral element. Numerical results demonstrate an improvement in the iteration count over the classical Schwarz algorithm.

Introduction

The classical Schwarz algorithm uses Dirichlet transmission conditions between subdomains. By introducing a more general Robin boundary condition, it is possible to optimize the convergence characteristics of the original algorithm [1, 2, 5, 4]. In this work, a study of the model equations $u - \Delta u = f$ and pseudo-Laplacian arising in incompressible flow solvers is performed. As suggested by the work of [3], the preconditioning is either implemented via a P_1 finite element formulation of the original problem build on the spectral element grid, or directly by solving a smaller spectral element problem without overlap on each spectral element.

Although traditional Schwarz preconditioning combined with a coarse grid solver is quite efficient, the need for even more powerful preconditioning techniques stems from atmospheric modeling. Recently (see [9, 7]), a semi-implicit SEM was combined with OIFS time stepping, enabling time steps on the order of 20 times the advective CFL condition [10]. This directly reflects as a significant increase in the number of conjugate gradient iterations required to perform the semi-implicit step.
