We develop and study symmetric multilevel preconditioners for the computation of the orthogonal spline collocation (OSC) solution of a Dirichlet boundary value problem (BVP) with a nonselfadjoint or an indefinite operator. The OSC solution is sought in the space of piecewise Hermite bicubic spline functions defined on a uniform partition. We consider an additive and a multiplicative multilevel preconditioners that are used with the preconditioned conjugate gradient (PCG) method. Let  $\Omega$  be a unit square  $(0,1)\times(0,1)$  with the boundary  $\partial\Omega$ , and let  $x=(x_1,x_2)$ . We consider a BVP

$$Lu \equiv \sum_{i,j=1}^{2} a_{ij}(x)u_{x_ix_j} + \sum_{i=1}^{2} b_i(x)u_{x_i} + c(x)u = f(x), \quad x \in \Omega, \quad u = 0 \text{ on } \partial\Omega.$$
(1)

Operator L could be non-selfadjoint or indefinite in  $L^2$ inner product. We assume that the principal part of L satisfies the uniform ellipticity condition and that BVP (1) has unique solution in  $H^2(\Omega)$ .Let  $\pi_0$  be a uniform coarsest rectangular partition of  $\Omega$ . We obtain a set of partitions  $\{\pi_k\}_{k=0}^K$  by standard coarsening, and let  $V_0 \subset V_1 \subset \ldots \subset V_K \equiv V_h$  be the set of corresponding nested spaces of piecewise Hermite bicubics that vanish on  $\partial \Omega$ . Let  $\sum$  denote the two-dimensional composite Gauss quadrature corresponding to partition  $\pi_h$  with 4 nodes in each element. Let  $\mathcal{G}_h$  denote the corresponding set of Gauss points. The OSC discretization of BVP(1) is defined by

$$u_h \in V_h, \quad Lu_h(\xi) = f(\xi), \quad \xi \in \mathcal{G}_h,$$
 (2)

and it can be written as the operator equation  $L_h u_h = f_h$  in the Hilbert space  $V_h$  with the inner product  $(v,w)_h = \sum vw$ . Let  $\{\psi_{k,j}\}_{j=1}^{N_k}$  be the standard finite element basis of  $V_k$  consisting of products of one-dimensional value and slope basis functions. Using space decomposition

$$V_h = V_0 + \sum_{k=1}^{J} \sum_{j=1}^{N_k} V_{k,j}, \quad V_{k,j} = \text{span}(\psi_{k,j}),$$

we define and study multilevel additive  $B_a$  and multiplicative  $B_m$  preconditioners for solving the normal equation  $L_h^*L_hu_h=L_h^*f_h$ , where  $L_h^*$  is the adjoint to  $L_h$ . The implementation of  $B_a$  and  $B_m$  is based on relationships between basis functions for two consecutive partitions and the implementation of  $B_m$  is similar to that for V(1,1)-cycle with the Gauss-Seidels moothing. A problem on the coarsest partition is assumed sufficiently small, and it is solved exactly. The computational cost of the preconditioning algorithms is  $O(N_K)$ . The following is our main result.

**Theorem 1** There are positive independent of h and K constants  $\alpha_a, \beta_a, \alpha_m, and \beta_m, such$  that

$$\alpha_{a} (B_{a}v, v)_{h} \leq (L_{h}^{*}L_{h}v, v)_{h} \leq \beta_{a} (B_{a}v, v)_{h}, \quad v \in V_{h},$$

$$\alpha_{m} (B_{m}v, v)_{h} \leq (L_{h}^{*}L_{h}v, v)_{h} \leq \beta_{m} (B_{m}v, v)_{h}, \quad v \in V_{h}.$$
(3)

We present numerical results that demonstrate the efficiency of our preconditioning algorithms.
