In this work we construct and analyze multigrid preconditioners for operators of the form $\mathcal{D}_\lambda + \mathcal{K}^*\mathcal{K}$, where $D_\lambda$ is the multiplication with a relatively "smooth" function $\lambda > 0$ and $\mathcal{K}$ is a discretization of a compact linear operator. These systems arise when applying interior point methods to the distributed optimal control problem $\min_u \frac{1}{2}(\|\mathcal{K}u - f\|^2 + \beta\|u\|^2)$ with box constraints $\underline{u} \le u \le \overline{u}$ on the control $u$. The presented preconditioning technique is related to the one developed by Drăgănescu and Dupont in [1] for the associated unconstrained problem, and is intended for large-scale problems. As in [1], the quality of the resulting preconditioners is shown to increase as $h \downarrow 0$ at a rate that is optimal with respect to $h$ if the meshes are uniform, but decreases as the smoothness of $\lambda$ declines. We test this algorithm first on a Tikhnov-regularized backward parabolic equation with $[0,1]$ constraints and then on the elliptic-constrained optimization problem

$$\text{minimize} \qquad \tfrac{1}{2}y - f^2 + \tfrac{\beta}{2}\|u\|^2$$

$$\text{subj. to} \qquad \Delta y = u \ , \ y \in H_0^1(\Omega), \ \underline{u} \le u \le \overline{u} \ \ a.e.$$

In both cases it is shown that the number of linear iterations per optimization step, as well as the total number of fine-scale matrix-vector multiplications is decreasing with increasing resolution, thus showing the method to be potentially very efficient for truly large-scale problems.
